POLYPS IN THE BOWEL
A polyp is a fleshy growth on the inside of the bowel. Some people may develop just a single polyp, while others can have two or more at a time.
Polyps can either be on a stalk (in which case the polyp looks like a mushroom growing up from the lining of the bowel) or they can be much flatter and even have quite a broad base. Polyps are benign (non cancerous) but they are important because some of them may eventually become malignant (cancerous). Most doctors think that all bowel cancers develop from polyps.

HOW COMMON ARE POLYPS?
Polyps seem to be very common indeed – especially for those of us who live in the West, possibly related to the Western diet. About one in four people will have a polyp at some time in their life. Polyps tend to be slightly more common in men than women. They are rather unusual below the age of 40 and seem to occur most often in people over the age of 60.

WHAT SORTS OF POLYPS ARE THERE?
Most polyps are small. They are usually less than one centimetre in size but can grow up to several centimetres. Usually the bowel only contains a single polyp but sometimes there can be more, although it is unusual to have more than five. Apart from coming in different shapes and sizes, polyps also vary in their appearances when looked at under a microscope. We realise that some types of polyp have no potential whatsoever to become cancers, but there are others that do. The polyp, which is most important to detect and treat, is called an adenoma.

WHY DO POLYPS APPEAR?
The lining of the bowel, like other organ linings, constantly renews itself throughout our lives. There are many millions of tiny cells in the lining, which grow, serve their purpose and die before new cells then take their place. Each of these millions of cells contains genes, which give instructions to the cell on how to behave and grow. When genes behave in a faulty manner, this can cause the cells to grow quicker, eventually producing a small bump on the bowel surface that we call a polyp.

WHY DO POLYPS GET BIGGER?
A polyp, or more strictly the particular type of polyp called an adenoma, starts out as a tiny bump on the surface of the bowel. The genes give faulty instructions that can make the cells grow more quickly, but do so in an orderly manner. Some polyps remain very small throughout their lives while others continue to enlarge. Most polyps remain benign throughout life but about 1 in 10 will turn into cancer. We believe that all malignancies of the bowel begin as benign polyps; so by removing benign polyps we can help to prevent the development of the rare ones that may become a cancer.

DO POLYPS CAUSE SYMPTOMS?
Usually polyps do not cause symptoms, and most people will never know if they have them. Polyps are often discovered at colonoscopy (see below) which may be done because there are bowel symptoms – the polyps are very rarely a cause of those symptoms. Occasionally they can cause bleeding from the back passage. Sometimes polyps produce an excess of mucus or slime, which can be noticed on motions when opening the bowel. Very occasionally a polyp can grow so large as to cause a blockage of the bowel but unless this occurs polyps do not cause pain.
HOW ARE POLYPS DIAGNOSED?
Polyps can be detected either by colonoscopy or by a barium enema x-ray. Both methods require the bowel to be as clear as possible before the procedure so you will be asked to follow a special diet as well as taking laxatives. Both techniques also involve a small tube being passed through the back passage.

In the case of a barium enema this is to allow a liquid to be passed into the bowel that will show up on x-rays: this test is rarely done nowadays.

In colonoscopy, a soft flexible tube is passed along the back passage and then through the whole colon. Sometimes a shorter instrument called a sigmoidoscope is used but this can only allow inspection of the lower colon. If the barium enema does reveal a polyp, a colonoscopy will then be needed to remove it.

WHY MIGHT I NEED INVESTIGATIONS OF THE BOWEL?
The most common reason to carry out an examination of the bowel is that a patient has noticed symptoms – particularly rectal bleeding.

However, increasingly, patients are being asked to give a sample of their stool for a chemical test which can detect small quantities of blood that are not visible. This test is called ‘faecal occult blood’ and is likely to be much more widely used over the next few years. The idea is that unsuspected polyps might bleed a little – not enough for the blood to be visible – but enough for it to be picked up on a chemical test of the motion. This can aid any potential diagnosis.

WHAT HAPPENS AFTER THE POLYP HAS BEEN REMOVED?
Once they have been removed all polyps are retrieved if possible, and sent to the laboratory for microscopic analysis. This will show whether or not the polyp has been completely removed, whether it has the potential to develop malignancy and, of course, to be sure that cancer has not already developed.

WHY SHOULD I EAT?
You can eat normally and do not need to follow a special diet. A healthy diet, which includes a wide variety of foods and plenty of fruit and vegetables, is good for your general health and bowel motions. Aim to have regular fruit and vegetable (with meals as well as snacks) and to drink at least 2 litres (8-10 cups) of fluid every day.

WHAT RESEARCH IS NEEDED ON POLYPS?
It is essential that we find out why such a relatively large number of people tend to form polyps. If we can do this, it should be possible to prevent polyps from forming. As we know that most, if not all, bowel cancers start as polyps, then it might be possible to prevent colon cancer from developing earlier if we knew how to prevent polyps forming. We need to learn the detail of what factors in our genes make us likely to form polyps. Much research is also needed on which dietary factors are important.

HOW ARE POLYPS TREATED?
There are a variety of different techniques to remove polyps but most consist of passing a wire through the colonoscope and looping the wire around the polyp - like a lasso - to remove it. This procedure is quite painless and only one examination is usually needed to clear the bowel of polyps. Occasionally, there may be too many polyps for all of them to be removed safely and the procedure may need to be repeated.

Conditions that affect the gut, the liver and the pancreas (collectively known as digestive diseases) are widespread but little known. They can cause significant health problems for people who live with them and, sadly, they are a factor in 1 in 8 UK deaths. Core is the only national charity working to change this by fighting all digestive diseases. As a charity, Core:

- Supports important medical research that looks for cures and for ways of improving the lives of patients;
- Provides evidence-based information that enables patients and families to understand and control their condition;
- Works to raise awareness of these conditions, their symptoms and impact.
